Comparison of exhaust emission from Euro 3 and Euro 6 motor vehicles fueled with petrol and LPG based on real driving conditions

Constantly increasing requirements regarding emission limits for harmful exhaust components force vehicle manufacturers to improve the construction of vehicle engines as well as exhaust gas cleaning systems. In addition to modifications in the field of technology of motor vehicles themselves, it is also important to study the impact of alternatives to petrol or diesel fuels. One of the most popular fossil fuels is liquid petroleum gas. In the paper, the results of comparative studies on the emission of harmful exhaust components of vehicles meeting the Euro 3 and Euro 6 standards in the field of petrol and LPG fuel use are presented. Emission measurement was performed using a portable emission measurement system from Horiba OBS-2200 under real traffic conditions. The presented results show the differences between the tested vehicles and the fuels used.

Key words: emission, PEMS, fuel, LPG, RDE

1. Introduction

In recent years, due to the constantly growing requirements regarding the emission policy, which must be met by car manufacturers, there has been a dynamic development of the construction of internal combustion engines as well as catalytic systems [3]. The main legislative objectives of the European Union concern the reduction of harmful effects on the surrounding environment, both on human health and climate change. The automotive sector is the main source of a different variety of air pollutants, eg hydrocarbons, nitrogen oxides, carbon monoxide, particulate matter as well as greenhouse gases, which include primarily carbon dioxide [2, 4–6, 8].

One of the alternative renewable fuels that have lower emissions of toxic compounds is LPG. LPG is acquired as a naturally occurring product of the natural gas extraction process or as an automatic result of the oil refining production process. LPG meets all four key objectives set by the EU in its guidelines for trans-European energy networks [7]. LPG is petroleum derived colourless gas, consists of propane or butane or from mixtures of both. In everyday usage different mixtures are used depending on the climatic nature of every region [11]. This gas is also characterized by a low price, which makes its popularity grows as an alternative to petrol and diesel.

The aim of the study was to determine the emission value of harmful exhaust components (CO₂, THC, NOₓ, CO) for vehicles meeting the Euro 3 and Euro 6 standards in the scope of petrol and LPG fueling. The emission measurement was made by using a portable emission measurement system for the selected route, which included the urban, rural and motorway part.

2. The methodology of the study

The road selected for testing, including the urban, rural and motorway part, is shown in Fig. 1. The route was 40 km long, while the rides were made in June 2018.

The PEMS Horiba OBS-2200 system was used to measure road emissions, the specifications of which are presented in Table 1. PEMS can be installed in the boot of the tested vehicle, while the measuring sensors with a flow meter are connected to the outlet pipe [12]. The exhaust gas pipe must be heated to 190°C to avoid condensation of hydrocarbons. In addition, ambient temperature and humidity sensors, as well as a GPS transmitter, are connected to the system [3]. In order to get a full picture of the impact of the engine operation on the generated emission, the OBDII interface [5, 13, 14] can be connected to the ECU of the vehicle. The RDE test was started by comparing the measurement from the PEMS system with the AMAi60 stationary exhaust gas analysis system. Initial tests were carried out on a chassis dynamometer built in a climate chamber on a passenger car. The test results showed that differences in the emission values of pollutants measured using the PEMS and AMAi60 systems, were within the permissible deviations. Therefore, further measurements of emissions in real traffic conditions can be considered as correct.

Vehicles used for road emission tests are shown in Fig. 2. The vehicle fulfilling the Euro 3 standard is characterized by a 1991 cm³ engine, it has manual transmissions, an MPI power system and a TWC catalytic system, while a vehicle meeting the Euro 6 standard has an 1149 cm³ engine, while the other described parameters are the same as the predecessor, both vehicles are fueled with petrol as well as LPG. On the day of testing, the Euro 3 car had a mileage of 260,000 km, while the Euro 6 was 42,000 km.

3. The road tests results

All 4 tests lasted for a similar time and amounted to around 2500 s, only the travel time for a Euro 3 vehicle fueled with gasoline in the charts is 3000 s, because for illustrative purposes, emissions during cold-start mode were not excluded. The graphs of specific distance emission at the end of the work for all tested harmful exhaust components are already for the engine warmed up. Fig. 3–6 shows the emission intensity of CO₂ for the tested vehicles fueled with petrol and LPG.

Fig. 3. Emission intensity of CO₂ for Euro 3 petrol fuelled vehicle

Fig. 4. Emission intensity of CO₂ for Euro 3 LPG fuelled vehicle

Fig. 5. Emission intensity of CO₂ for Euro 6 petrol fuelled vehicle

Fig. 6. Emission intensity of CO₂ for Euro 6 LPG fuelled vehicle
Based on Fig. 3–6, it is visible that:

- in relation to Fig. 3, which also has data regarding the cold-start (first 250 s), it can be noticed that the CO₂ emission intensity and its increase as a result of the engine’s operating temperature is not so significant compared to other exhaust components, e.g. THC, NOₓ,
- the highest CO₂ emission intensity occurs while vehicle speed increase and sudden acceleration,
- the highest CO₂ emission intensity values for all researched cases are for the motorway section, this is related to high speeds on such sections of roads,
- CO₂ emissions intensity for tested LPG-powered vehicles are lower compared to petrol: for Euro 3 vehicle approx. 15%, and for Euro 6 approx. 18%.

Figures 7–10 show the emission of THC for both vehicles tested, fueled with LPG and petrol. As in the previous case, the graph for a petrol-powered Euro 3 vehicle also contains data on the engine’s heating phase. Based on the THC emission graphs, it can be observed that:

- the largest part of THC emissions is related to the cold-start of the engine and it accounts for about 66% of the total emissions for the whole ride,
- for the Euro 3 vehicle fueled with LPG, the highest increase in THC emissions occurs for the urban part, while the subsequent parts are characterized by a similarly steady upward trend in emissions,
- for the Euro 6 vehicle fueled both by petrol and LPG, the largest increase in THC emissions occurs for the motorway part and it is the majority of the emission generated during the travel along the test route,
- THC emission for both the Euro 6 and Euro 3 vehicles is lower for LPG than for petrol.

Graphs of NOₓ emissions intensity as a function of acceleration and velocity are presented in Fig. 11–14.
Comparison of exhaust emission from Euro3 and Euro6 motor vehicles fueled with petrol and LPG based on real driving conditions

Based on the NOx emission intensity graphs shown in Figs 11–14, it can be seen, that:

- the largest NOx emission intensity for petrol fueled Euro 3 vehicle occurs in the low speed range and temporarily during acceleration of speeds higher than 80 km/h, while for LPG higher NOx emissions intensity occur for speeds higher than 50 km/h during acceleration of the vehicle,

- for the Euro 6 vehicle, the NOx emission intensity for petrol shows only temporary higher values at speeds of around 50 km/h, while in the range of other speeds/accelerations it is relatively low; for LPG, higher NOx emission intensity values occur in a wider range of speed and acceleration of the vehicle.

Figs 15–18 presents specific distance emission for harmful emission components. The results for NOx, CO and THC were compiled to emission limits valid for a given vehicle emission standard.
Analyzing the data contained in Fig. 15-18, it can be noted that:
- for all trips the highest CO$_2$ emission values occurred for the motorway section, this is related to the highest fuel consumption by the tested vehicles at high speed,
- exceeding the Euro 3 and Euro 6 standards limits occurred for CO in the area of passage through the motorway section, the remaining parts of the route and specific distance emissions emitted on them are relatively low,
- exceeding the Euro standard limits for NO$_x$ occurred for the Euro 6 vehicle in the following parts of the test: for petrol – urban, motorway, and for LPG – urban,
- THC specific distance emission reaches the highest values for the Euro 3 vehicle in the petrol range, exceeding the limits for this road test takes place in the urban and motorway part.

4. Conclusions
The results of comparative emission tests for vehicles complying with the Euro 3 and Euro 6 standards fuelled by petrol and LPG presented in the work indicate:

- lower CO$_2$ specific distance emissions for the Euro 6 vehicle compared to Euro 3 for all road parts, for petrol for the urban part by approx. 25%, rural for approx. 22%, motorway approx. 26%, and for LPG for part of the city about 47%, rural about 20% and motorway about 42%,
- much lower CO specific distance emission of the Euro 6 vehicle in relation to Euro 3, mainly in the aspect of motorway section, which is approximately 4 times smaller for petrol, and 2 times for LPG,
- lower NO$_x$ specific distance emission for the Euro 6 vehicle compared to Euro 3, mainly in the aspect of rural and motorway parts for LPG fueling,
- several times lower THC specific distance emission for both petrol and LPG, for Euro 6 vehicle in relation to Euro 3.

In most cases, the parts of the test within one type of vehicle show the advantage of LPG in relation to petrol in terms of emission of harmful exhaust components.

The presented comparative results of the tested vehicles are indicative and cannot be taken unequivocally, as both vehicles have different mass as well as the used drive unit and the catalytic system. Valuable results can be those within one vehicle in the range of comparison of petrol to LPG.

Certainly, the emission data provided depends also on the driver’s driving style and prevailing traffic conditions, which may lead to certain limitations and inaccuracies, but it is important to conduct this type of research because it is crucial to know the amount of emission taking place in the real driving. In fact, every road test is unique. These data are valuable especially in the aspect of learning about the real road emissions, as well as provide the possibility of later use for the development of various types of emission models of fumes pollution [1, 9, 10].

Based on the emission results it can be said, that the LPG represents a good fuel alternative for petrol and therefore it must be taken into consideration in the future of large-scale personal transport.
